1. Introduction

A cost and benefit analysis including a sensitivity analysis was made to evaluate the proposed project in terms of its economic viability. The project benefits, namely, incremental benefits to be generated by the project, and the project costs were estimated in economic terms for the analysis. The overall framework of the project evaluation, results of the estimation of the project benefits, calculation of the economic project costs, and evaluation of the cost and benefit analysis are described in the sections below.

Overall Framework of Project Evaluation

| Items | Description |
|---|---|
| 1) Evaluation Method | A cost and benefit analysis is used for assessment of the project viability. In particular, Economic Internal Rate of Return (EIRR) and the benefit, cost ratio (B/C ratio) and net present values (NPV) are used as indicators for evaluation. |
| 2) Project Benefits used for Evaluation | <p>The following three types of project outcomes are counted as project benefits.</p> <ul style="list-style-type: none"> - Reduced CO₂ emission through reduction of deforestation and forest degradation by the project* - Increased livelihoods opportunities of local communities participating in hands-on training courses of Activity 2.1.1** - Absorbed CO₂ from the atmosphere through implementation of reforestation/ afforestation micro program whose areas could be used for carbon offsetting projects <p>* Only the benefits from the reduced CO₂ emissions through reduction of forest degradation is estimated in the evaluation since forest degradation or conversion of dense forests is considered as the major source of CO₂ emissions in the country.</p> <p>**For estimation purpose, the agricultural benefit to be generated from training courses on climate resilient agriculture is estimated and used as the benefit of increased livelihood opportunities.</p> |
| 3) Project Cost | Direct project costs and indirect costs except government staff salary are counted as the project costs for the analysis. |
| 4) Inflation | The influence of inflation is not considered in the estimation of the benefits and costs in the future. Likewise, taxes and government subsidies are excluded from the estimation of the project economic cost and benefit. |
| 5) Discount rate | <p>A discount rate of 11.87% is adopted for the calculation of the net present values of the project benefits and costs referring to the average real interest rate in Timor-Leste for the last five years, which is published by World Bank¹. Although the real interest rate may not necessarily be used as the discount rate for the investment project in Timor-Leste due to market distortions, the rate of 11.87% is still justifiable because of the following reasons:</p> <ol style="list-style-type: none"> 1) ADB has used 12% as the standard discount rate for any public investment projects in the region until recently. 2) The standard discount rate is now replaced with 9% considering the economic development in the counties in the region. However, Timor-Leste is one of the counties newly established and still categorized as the least developing countries. The 12% is considered still appropriate. 3) The proposed project can be categorized as a social-targeting and environmental protection project, which justify a lower rate (i.e., 6% in the ADB guidelines); hence the evaluation with 11.87% is considered as more conservative. |
| 6) Conversion factor | <p>To correct the price distortion, the conversion factor is to be used for estimation of the project cost. In general, Timor-Leste imports goods with tariff much more than exports the products. Hence, the standard conversion factor (SCF), which much be less than 1.0, should be applied for estimation of appropriate economic values of the project cost. Nevertheless, as the proposed project plan to use few imported/ exported/ subsidized items or goods for implementation of the Activities unlike an infrastructure development project, <u>the SCF of 1.0 is used for simple and quick but conservative assessment.</u></p> <p>By correcting the price distortion, the total estimated amount of the economic project cost would be lower than financial ones. Hence, the use of the SCF of 1.0 means that</p> |

¹ Real interest rate was referred to the data published by World Bank at the URL/<https://data.worldbank.org/>.

| Items | Description | | |
|---|--|--|---|
| | the cost-benefit analysis is made in a conservative way. | | |
| 7) Evaluation period | The evaluation period is set as 20 years, which is the same as the project life. | | |
| 8) With-project and without-project conditions for estimation of the project benefits | The project benefits were estimated by comparing “the area of dense forest”, “the production of maize” and “carbon sequestration by afforestation” under the “with-project” and “without project” conditions. The following table shows the basic assumptions in the changes of forest status and agricultural production with-project and without-project conditions. | | |
| | Benefit | With-Project Conditions | Without-Project Conditions |
| | Area of dense forest | The reduction rates of dense forest will decline in villages where the village-level NRM or CBNRM mechanism is in place. | The reduction rates of dense forest will be maintained as it is. The degradation rates between 2003 and 2012 is used as the BAU scenario. The VCS methodology (VM0006) is referred to estimate the degradation rate of dense forests. |
| | Agricultural production | Yield of maize produced by trained farmers/ families of Activity 2.1.1 (households who participate in Activity 2.1.1) will increase after the training courses on climate smart agriculture. | Yield of maize produced by households will be maintained as the status quo. It may range from 0.3 ~ 2.0 ton/ha in the target watersheds based on the sampled survey done in 2018/2019. |
| | Carbon sequestration by afforestation | Trees planted by reforestation/ afforestation micro program of Activity 2.1.1 will be properly managed by the community. | Reforestation/ afforestation micro program will not be implemented in the target villages. |

Source: JICA (2020)

In addition to the economic analysis, the possible contribution to the reduction of CO₂ emission from reduction of deforestation is estimated in Chapter 5 of this report. The methodology for calculating the mitigation impacts follows the general guidance of the Intergovernmental Panel on Climate Change (IPCC) as described in the 2006 Guidelines for national GHG inventories and the 2003 Good Practice Guidance for LULUCF that provides sector-specific recommendations. For a project level methodology, VCS methodology (VM0006) was referred to estimate the deforestation rate in the target watersheds to set the baseline trend.

2. Economic Benefit of the Project

2.1 Summary of the Results of Estimation of Economic Benefits

The following benefits were estimated and converted into monetary value. Since the conversion of dense forests or forest degradation is considered as the major source of CO₂ emissions in the country as described in Chapters 3 and 6, the focus of the benefit assessment on the reduced CO₂ emissions was placed on those from reduction of forest degradation in this evaluation.

- Benefits from reduced CO₂ emission through reduction of forest degradation of dense forests in the project villages
- Benefits from increased maize production in the farms of trained farmers in the project villages

- c. Benefits from carbon sequestration by reforestation/ afforestation micro program in the project villages

The methodologies of estimating and calculating the monetary values of the respective benefits are summarized below.

| Summary of Methodologies for Estimation of the Project Benefits | |
|---|--|
| Type of benefits | Outline of Calculation |
| Reduced CO ₂ emission | <p>➤ Summary description of the methodology on Project benefits Project benefits from Reduced CO₂ emission = $\sum (\text{Changes in dense forests under the "with-project" and "without-project" conditions} \times (\text{Average carbon stock of dense forest} - \text{Average carbon stock of sparse forest}) \times \text{unit price of CO}_2 \text{ at the carbon market})$</p> <p>Summary of the equation:</p> $ER_y = (A_{B,y} - A_{D,y}) \times (NT_D - NT_S) \times 44/12 \times (1 - DF)$ <p>ER_y = Net anthropogenic GHG emission reduction by the project in year y (t-CO₂e/y)</p> <p>$A_{B,y}$ = The area of stratum D in year y based on the baseline assumption within the project area (ha)</p> <p>$A_{D,y}$ = The area of stratum D in year y within the project area (ha)</p> <p>NT_D = Carbon stock in the stratum D 'dense forest' in year y (t-C/ha)</p> <p>NT_S = Carbon stock in the stratum S 'sparse forest' in year y (t-C/ha)</p> <p>DF = Discount factor (20% was applied as a conservative accounting, comparing with other project level application, such as the JCM-REDD+ Cambodia as 20%, and VCS project ranging from 15-30%.)</p> <p>➤ Project Boundary:</p> <ul style="list-style-type: none"> • The spatial extent of the project boundary encompasses the project village areas. • GHG sources included in the project boundary: CO₂ (CH₄ and N₂O are excluded). • Carbon pool included in the project boundary: Above-ground biomass and Below-ground biomass. (Dead wood, litter, soil organic carbon, and wood products are excluded.) • Forest definition: 'Dense forest' is defined as a land with tree crown cover of more than 60% and more than 0.5 ha. 'Sparse forest' is defined as a land with tree crown cover of more than 10% and more than 0.5 ha.² • Leakage: Migration of many farmers and farming activities out of the project boundary is not assumed in the course of the project implementation. <p>➤ Assumptions:</p> <ol style="list-style-type: none"> 1) The area of dense forests under "with-project" condition is estimated by assuming that the degradation rate would be reduced gradually and stopped 5 years after the village regulations are in place in the project villages; 2) The area of dense forests under "without-project" condition (the baseline scenario) is estimated by assuming that dense forest would be reduced at the current degradation rates of 3.5% ~ 8.6% p.a. of the respective watersheds (5.8% p.a. on average). 3) Average carbon stock of dense forest is 272.4 tC or 998.1 tCO_{2eq} per ha³; 4) Average carbon stock of sparse forest is 97.9 tC or 358.9 tCO_{2eq} per ha³; and 5) Unit price of t-CO_{2eq} of US\$ 4.2/t CO_{2eq}⁴ was applied, which is the average price |

² Refer to the definition used by the National Forest Conservation Plan, JICS, 2012 with adjustment based on FAO definition (FRA 2015, Terms and Definitions).

³ Carbon stock was calculated by using the volume equation form proposed by FAO and default value from IPCC Guidelines for National Greenhouse Gas Inventories (2006) and Good Practice Guidance for Land Use, Land-Use Change and Forestry (2003).

| Type of benefits | Outline of Calculation |
|--|---|
| | <p>of carbon credit for REDD+ project in 2016, as a conservative accounting given the GCF REDD+ Result Based Payment pilot phase and other international recognized forest carbon price is US\$ 5/t CO_{2eq}.</p> <p>The estimated reduction of CO₂ emissions is adjusted by the discount factor of 20% in consideration of the potential risk of reversals of net emission reduction due to unexpected events or changes of internal/external conditions.</p> <p>The potential leakage is assumed to be zero, since the village-level NRM regulations with continuous governance capacity enhancement as well as local livelihood improvement is expected to cause a behavioural change among local communities in the target villages. Operations of the watershed management councils at post-administrative level will enhance the village level mechanism and result in the reduction of inter-village cases of illegal cutting, wildfires, and animal grazing in the sub-watersheds/ posts-administrative. As for firewood collection for household consumption, local communities in the target villages collect dead trees/ fallen branches and/or prune branches of shade trees in coffee plantations and regenerated trees in fallow areas for shifting cultivation. Thus, the introduction of the village-level regulations is not expected to affect their firewood collection practices or cause any shifting of firewood collection activities to existing forests, particularly dense forests, in the target villages. If anything, the project activities of Activities 2.1.1 (micro programs) and 2.3.1 (CF) will enable local communities to sustainably produce firewood trees in their own lands through reforestation, production of fodder trees, and introduction improved silvicultural practices.</p> |
| Increased maize production | <p>➤ Summary description of the methodology on Project benefits Increased maize production = $\sum((\text{Changes in maize yield under the "with-project" and "without-project" conditions} \times \text{Average unit farmgate price of maize} - \text{Balance amount of the production costs under the "with-project" and "without-project" conditions}) \times \text{total area of trained farmers' farms})$</p> <p>➤ Assumptions:</p> <ol style="list-style-type: none"> 1) Maize yield would increase up to 1.5 ton/ha in Laclo and Comoro watersheds (northern parts of the country) and 2.4 ton/ha in Tafara and caraulun watersheds (central and southern parts of the country) one year after 2-year hands-on training courses end in the project villages; 2) Average unit farmgate price of maize is US\$ 0.75/ kg; 3) Balance amount of the production costs under both the conditions is estimated by calculating the increased cost of farm laborers; and 4) Total area of farms used by trained farms is estimated by multiplying the number of trained farmers (120 households/village) with the average maize cropping area of household (0.5 ha/household). |
| Carbon sequestration by reforestation/ afforestation | <p>➤ Summary description of the methodology on Project benefits Project benefits from carbon sequestration by reforestation/ afforestation = $\sum(\text{Changes in carbon stock of planted trees}) \times \text{unit price of CO}_2 \text{ at the carbon market})$</p> <p>➤ Assumptions:</p> <ol style="list-style-type: none"> 1) Changes in carbon stock of trees planted by the micro program is estimated by referring to the existing carbon offset project in Timor-Leste. The basic conditions of the existing project are as follows: <ul style="list-style-type: none"> ✓ Tree species: Casuarina angustifolia, Swietenia macrophylla, Gmelina arborea, Tectona grandis, Paraserianthes falcataria and Gliricidia sepium ✓ Carbon pools: Tree biomass (Above and below ground), soil organic carbon, long lived harvested products, litter and dead wood ✓ 15% of risk buffer was applied. ✓ Risk level of leakage was considered low and set zero. 2) Unit price of t-CO_{2eq} of US\$ 8.1/t CO_{2eq} was applied, which was the average price of carbon credit for afforestation/reforestation project in 2016. |

⁴ State of the Voluntary Carbon Markets 2017.

Source: JICA (2020)

The total values of the economic benefits generated in each watershed over the project life span are summarized below.

| Summary of the Economic Benefits | | |
|----------------------------------|--|------------------------|
| Watershed | Type of benefits | Total estimated values |
| Laclo | Reduced CO ₂ emission | US\$ 7,806,212 |
| | Increase of maize production | US\$ 17,652,240 |
| | Carbon sequestration by reforestation/ afforestation | US\$ 48,058 |
| Comoro | Reduced CO ₂ emission | US\$ 2,253,640 |
| | Increase of maize production | US\$ 6,999,960 |
| | Carbon sequestration by reforestation/ afforestation | US\$ 21,357 |
| Tafara | Reduced CO ₂ emission | US\$ 2,301,449 |
| | Increase of maize production | US\$ 2,699,640 |
| | Carbon sequestration by reforestation/ afforestation | US\$ 16,021 |
| Caraulun | Reduced CO ₂ emission | US\$ 6,182,045 |
| | Increase of maize production | US\$ 5,165,340 |
| | Carbon sequestration by reforestation/ afforestation | US\$ 37,377 |
| Overall | Reduced CO ₂ emission | US\$ 18,543,346 |
| | Increase of maize production | US\$ 32,517,180 |
| | Carbon sequestration by reforestation/ afforestation | US\$ 122,813 |

Source: JICA (2020)

Details of the calculation of the project benefits are further described in the following sections.

2.2 Benefits from Reduced CO₂ Emissions through Reduction of Forest Degradation

2.2.1 Reduction of Forest Degradation

As indicated in Section 5.3 of the Pre-FS, the impact assessment survey conducted by the JICA CBNRM Project reveals that the project activities of Activities 1.1.1, 1.2.1 and 1.2.2, namely i) participatory formulation of village regulations, ii) continuous capacity building for sustainable village level governance, and iii) enhancement of adaptive management capacity at post-administrative level, could drastically reduce the degradation rate.

It was, therefore, assumed that the forest degradation rates of 3.5~8.6%/year of the respective target watersheds (5.8 %/year on average) would be constantly reduced at a rate of 20% annually after completion of PLUP and cut to zero within 5 years after PLUP under the “with-project” condition. In contrast, the areas of dense forests in the four watersheds were presumed to constantly reduce at the same degradation rates observed between 2003 and 2012 under the “without-project” condition.

The following table shows the effect of reduction of forest degradation by implementation of PLUP or Activities 1.1.1 and 1.2.1 in the target watersheds under the assumption explained above.

| Effects of reducing forest degradation under with-project conditions | | | | | | | | | | | | |
|--|--|--------|--------|----------|---|--------|--------|----------|--|--------|--------|----------|
| Year | Number of villages to be introduced PLUP in the watersheds | | | | Total areas to be introduced PLUP in the watersheds (%) | | | | Reduction rate of forest degradation in the watersheds (%) | | | |
| | Laclo | Comoro | Tafara | Caraulun | Laclo | Comoro | Tafara | Caraulun | Laclo | Comoro | Tafara | Caraulun |
| 2021 | 5 | 4 | 1 | 3 | 13.7 | 17.5 | 8.8 | 11.6 | 0.0 | 0.0 | 0.0 | 0.0 |
| 2022 | 8 | 4 | 3 | 5 | 35.6 | 34.9 | 35.2 | 30.8 | 2.7 | 3.5 | 1.8 | 2.3 |
| 2023 | 9 | 3 | 3 | 6 | 60.3 | 48.0 | 61.6 | 53.9 | 9.9 | 10.5 | 8.8 | 8.5 |
| 2024 | 8 | 3 | 3 | 6 | 82.2 | 61.1 | 88.0 | 77.1 | 21.9 | 20.1 | 21.1 | 19.3 |

Source: JICA (2020)

Areas of dense forests under the “with-project” condition were estimated by multiplying the reduction rate of forest degradation indicated above with the annual incremental areas of degraded forests in the respective target watersheds under the “without-project” conditions. The results of the estimation are shown below.

Areas of Dense Forests in the Target Watersheds under the With-Project and Without-Project Conditions
(unit: ha)

| Year | With-Project Condition | | | | | Without-Project Condition | | | | |
|------|------------------------|--------|--------|----------|--------|---------------------------|--------|--------|----------|--------|

Hence the area of dense forest protected by the project was estimated by calculating difference in dense forest areas under the “with-project” and “without-project” conditions. The following is the calculation formula used for estimation.

$$\text{Areas of dense forest protected} = \text{Areas of dense forest with-project} - \text{Areas of dense forest without-project}$$

As indicated in the table below, approximately 2,000 ha of dense forest is expected to be protected by the project at the end of the project in 2027, and more than 8,600 ha of dense forest can be protected from forest degradation during the project life span (by 2040).

Dense Forest protected by the Project

Source: JICA (2020)

In the estimation above, the potential leakage was assumed to be zero as the village-level NRM regulations with continuous governance capacity enhancement as well as local livelihood improvement is expected to cause a behavioural change among local communities in the target villages. The watershed management councils to be formed and operated in Activity 1.2.2 will also function as a coordination body to address and minimize inter-village issues, particularly the incidence of wildfire, illegal logging, and animal grazing.

2.2.2 Average Carbon Stock of Dense and Sparse Forests

Carbon stocks, which were further converted into CO₂ equivalent, of dense and sparse forests were estimated, respectively. Above-ground and below-ground tree biomasses were counted as major carbon pools of dense and sparse forests. Other carbon pools, i.e., above-ground non-tree biomass, dead wood, litter and soil organic carbon, were not used in the estimation due to a lack of data and also for conservative estimation.

In order to estimate the average stocks in the respective types of forests, the NDFWM and NDNC technical officials and forest guards of the respective municipalities concerned conducted the forest inventory survey with technical assistance from the JICA CBNRM Project Phase II from July 2019 to January 2020. To supplement the survey results, data of the Forest Conservation Plan (2012) were also fully used for estimation. As shown in the table below, the average CO₂ stocks of dense and sparse forests are estimated at 998.1 ton CO_{2eq}/ha and 358.9 ton CO_{2eq}/ha, respectively.

Average Carbon and CO₂ Stocks in Dense and Sparse Forests in the Watersheds

| Watersheds | Dense forest <1 | | Sparse forest | | Balance |
|------------|--------------------------|--|--------------------------|--|--|
| | Carbon stock (t C/ha) | CO ₂ stock (t CO _{2eq} /ha) | Carbon stock (t C/ha) | CO ₂ stock (t CO _{2eq} /ha) | CO ₂ stock (t CO _{2eq} /ha) |
| Laclo | 281.4 | 1031.8 | 88.3 | 323.6 | 708.2 |
| Comoro | 241.8 | 886.5 | 75.8 | 277.8 | 608.7 |
| Tafara | 276.7 | 1014.4 | 127.7 | 468.2 | 546.2 |
| Caraulun | 289.0 | 1059.7 | 99.9 | 366.2 | 693.5 |
| Average | 272.2 | 998.1 | 97.9 | 358.9 | 639.2 |

Note: CO₂ stock is calculated by multiplying 3.67 with the carbon stocks.

2.2.3 Estimation of Reduced CO₂ Emission from Dense Forests

The potential reduced CO₂ emission was estimated by assessing the differences in CO₂ emissions from degradation of dense forest (conversion of dense forest into sparse forest) in the target watersheds under the “with-project” and “without-project” scenarios.

(1) Without-project Scenario (Baseline Scenario)

CO₂ emissions of the baseline scenario from forest degradation in the target watersheds are tabulated below. As shown below, a total of 10.8 million tCO_{2eq} will be emitted from forest degradation in the next 20 years.

CO₂ Emission from forest degradation in the Target Watersheds under the without-project condition
(unit: tCO_{2eq})

| Year | Laclo | Comoro | Tafara | Caraulun | Total |
|-------|-----------|-----------|-----------|-----------|------------|
| 2021 | 275,117 | 135,986 | 136,558 | 349,532 | 897,193 |

(2) With-project Scenario (Project Scenario)

It was assumed that dense forests located in the project villages, 74 villages in the target watersheds in total, would be protected from degradation under the “with-project” scenario. As mentioned in the previous section, PLUP is expected to exert a reduction effect on forest degradation from the following year after PLUP. The calculation was made on the assumption that the forest degradation rate would be constantly reduced by 20% annually and become 0% from the 6th year. The following table shows that estimated CO₂ emissions of project scenario

CO₂ Emissions from forest degradation in the Target Watersheds under the with-project condition

(3) Estimation of Reduced CO₂ Emissions

The reduced CO₂ emissions in the target watersheds were calculated by assessing the differences in CO₂ emissions under the “with-project” and “without-project” scenarios. The formula used for calculation is shown below.

$$\text{Reduced CO}_2 \text{ emission} = \text{CO}_2 \text{ emission under the with-project condition} - \text{CO}_2 \text{ emission under the without-project condition}$$

Annual CO₂ emissions are expected to be reduced by approximately 21,369 ~ 431,757 ton CO₂ as shown in the table below.

Estimated Reduction of CO₂ Emission in the Target Watersheds

(unit: tCO₂)

| Year | Laclo | Comoro | Tafara | Caraulun | Total |
|-------|-----------|---------|---------|-----------|-----------|
| 2021 | 0 | 0 | 0 | 0 | 0 |

Source: JICA (2020)

(4) Adjustment of the Reduced CO₂ Emissions

The reduced CO₂ emissions estimated above as a result of the project interventions were adjusted by the discount factor of 20%⁵ in consideration of the potential risks of reversals of net emission reduction due to unexpected events or changes of internal and external conditions of the project. The following formula was used for adjustment.

$$\text{CO}_2 \text{ emission reductions} = \text{Reduced CO}_2 \text{ emissions} \times (1 - \text{discount factor (20\%)})$$

The results of the adjustment are tabulated below. The reduced CO₂ emissions are estimated at 17,095 ~ 345,406 ton CO_{2eq}/year. Around 4.4 million tCO₂ eq will be reduced from forest degradation by the project interventions over the project life span. The estimated project cost

⁵ The factor was decided on the basis of the existing cases of REDD+ projects in south east Asian countries.

(including co-finance) per tCO₂eq is, therefore, estimated at US\$3.38 per tCO₂eq for this project overall.

Estimated CO₂ emission reductions to be credited in the Target Watersheds

(unit: tCO₂)

(5) Benefits from Reduced CO₂ Emission

The reduced CO₂ emissions were converted into the monetary values by using the market carbon price of US\$ 4.2/ t CO₂, which is used for REDD+ project in the voluntary carbon market in 2016⁶, to estimate the project benefits from reduced CO₂ emissions. The calculation formula used for estimation is shown below.

$$\text{Benefits from CO}_2 \text{ Reduction} = \text{Estimated CO}_2 \text{ emission reductions to be credited} \times \text{USD } 4.2/\text{t CO}_2$$

The estimated annual incremental benefits from reduced CO₂ emission through reduction of forest degradation of dense forest in the target watersheds are shown below. The total benefit from CO₂ reduction during the project life span is estimated at US\$ 18,543,346.

Annual and Total Benefits from CO₂ Reduction through Protection of Dense Forests

2.3 Benefits from Increased Maize Production in Trained Farmers' Farms

2.3.1 Estimation of Increased Maize Yields under the With-Project and Without-Project Conditions

Maize yield under the with-project condition was estimated by fully referring to the results of the impact survey made by the JICA. The same survey indicated that the project interventions, namely enhancement of local capacity for climate resilient agriculture through hands-on training, would increase maize yield by 1.5 ton/ha even under the unfavorable weather conditions in the drier areas and 2.4 ton/ha under the normal weather conditions in the same areas.

Consequently, the potential increase of yield which trained farmers could achieve was set at 1.5 ton/ha in Laclo and Comoro watershed and 2.4 ton/ha in Tafara and Caraulun watersheds for conservative estimation of the total incremental maize production. It was also assumed that the yield would achieve 50% of the target in the 2nd year (or the last year) of the training courses and 100% of the same in the 3rd year (or one year after the end of the training courses) in the target villages.

2.3.2 Estimation of Crop Budgets under the With-Project and Without-Project Conditions

Crop budgets of maize production by trained farmers under the with-project and without-project conditions were also estimated by converting maize production and family labor cost into monetary values. The table below compares the estimated crop budgets per household between the with-project and without-project conditions, taking into account the opportunity costs for crop production in shifting cultivation areas by households who convert the farming practices.

Estimated Crop Budgets for Laclo and Comoro watersheds

| Items | Under the with-project condition | | | | | Under the without-project condition | | | | | | | Incremental Benefit =1)-2)-3) (USD/hh) |
|----------------------------|--|-------------|----------------|-------------------|-------------------|-------------------------------------|-------------|----------------|-------------------|-------------------|---|-------------------|--|
| | Value from land with Climate-resilient agriculture | | | | | Value from the existing land | | | | | Opportunity cost of giving up shifting cultivation*** | | |

Source: JICA (2020)

Any farm inputs except family laborers were not counted in the estimation of crop budgets, as no external input, such as commercial fertilizer or agrochemical, is used for maize production under both the conditions.

In the estimation given above, the average farmgate prices of maize and family labor were set at USD 0.75/ kg and USD 4.0/MD, respectively. The incremental benefits per household (HH) in the 3rd year and afterwards were estimated at USD 346/HH in Laclo and Comoro watersheds, USD 158/HH in Tafara and Caraulun watersheds.

2.3.3 Estimation of Total Beneficiaries and Areas used for Maize Production

It was assumed that all the 68 villages covered by Activity 2.1.1 would choose “climate resilient agriculture” as the topics of hands-on training on climate change adaptation measure and 120 HHs/ families in each village would take part in the training courses. Hence, 120 farmers/ families per village and 8,160 HHs/ families in total are expected to learn climate resilient agriculture techniques through the 2-year training courses. (8,160 HHs = 120 families/village x 68 villages)

Assuming that each trained farmer would apply the learned techniques to 0.5 ha of their farms for upland crop production, it was estimated that 60 ha of upland farms per village or 4,080 ha of upland farms in total will be used for maize production with climate resilient agriculture techniques.

2.3.4 Estimation of Benefit from Increased Maize Production

The total incremental benefits in the target watersheds were estimated by summing up those of the target villages according to the work schedule of Activity 2.1.1. The results of the calculation are summarized below. The total benefit during evaluation period is US\$ 32,517,180.

Benefit from yield increase of agricultural products

(unit: US\$)

2.4 Benefits from Carbon Sequestration by Reforestation/ Afforestation activities

2.4.1 Net Benefit of Carbon Sequestration by Reforestation/ Afforestation

The amount of carbon dioxide absorption of trees planted by reforestation/ afforestation micro program under Activity 2.1.1 was estimated by fully referring to the existing carbon offset project named “Halo Verde Timor Community Forest Carbon project” in Timor-Leste. The project planted 6 tree species about 75 ha in 9 villages in Manatuto Municipality. The estimated average net benefits from the plantations for 20 years are tabulated below.

| Average net benefit reported by Halo Verde Timor Community Forest Carbon project | | |
|--|--|--|
| Age of planted tree (year) | Average net benefit (tCO ₂ /ha) | Annual net benefit (tCO ₂ /ha/year) |
| 1 | 8.4 | 8.4 |
| 2 | 13.9 | 5.5 |
| 3 | 19.7 | 5.8 |
| 4 | 25.4 | 5.7 |
| 5 | 30.7 | 5.3 |
| 6 | 36.1 | 5.4 |
| 7 | 41.8 | 5.7 |
| 8 | 46.8 | 5.0 |
| 9 | 52.4 | 5.6 |
| 10 | 58.2 | 5.8 |
| 11 | 64.0 | 5.8 |
| 12 | 70.1 | 6.1 |
| 13 | 75.9 | 5.8 |
| 14 | 82.4 | 6.5 |
| 15 | 89.4 | 7.0 |
| 16 | 96.9 | 7.5 |
| 17 | 104.9 | 8.0 |
| 18 | 113.5 | 8.6 |
| 19 | 122.6 | 9.1 |
| 20 | 132.4 | 9.8 |

Source: Project Design Document of Halo Verde Timor Community Forest Carbon (2020)

The same assumptions and estimation employed by the Halo Verde Timor Community Forest Carbon project were used for estimation of carbon sequestration by plantations developed by reforestation/ afforestation micro program of the proposed project.

2.4.2 Plantation Area of Community Nursery and Reforestation program

Assuming that reforestation/ afforestation micro program will be implemented in one third of the target villages or 23 villages in the target watersheds and each village will develop a total of 8 ha of new plantation, which is the same size as the villages of the Halo Verde Timor

Community Forest Carbon project developed, the total plantation areas to be developed in the respective watersheds are estimated as shown below.

Plantation area for reforestation/ afforestation activities

| Watersheds | Target villages for Activity 2.1.1 | No of villages targeted by Refo/Affo MP | Plantation area (ha) |
|------------|------------------------------------|---|----------------------|
| Laclo | 28 | 9 | 72 |
| Comoro | 11 | 4 | 32 |
| Tafara | 10 | 3 | 24 |
| Caraulun | 19 | 7 | 56 |
| Average | 68 | 23 | 184 |

2.4.3 Estimation of Benefits from Carbon Sequestration by Reforestation/ Afforestation

(1) Estimation of CO₂ absorption from the atmosphere

The amount of carbon sequestration by reforestation/ afforestation in the target watersheds were calculated by multiplying annual net CO₂ absorption with the estimated plantation area of each watershed. The formula used for calculation is shown below.

$$\text{Estimated CO}_2 \text{ absorption from the atmosphere} = \text{Annual net CO}_2 \text{ absorption of existing carbon offset project} \times \text{Plantation area of each watershed}$$

Annual CO₂ absorption from the atmosphere is expected to be reduced by approximately 920 ~ 1,546 ton CO₂ as shown in the table below.

Estimated CO₂ absorption from the atmosphere by reforestation/ afforestation in the Target Watersheds
(unit: tCO₂)

| Year | Laclo | Comoro | Tafara | Caraulun | Total |
|-------|-------|--------|--------|----------|--------|
| 2021 | 0 | 0 | 0 | 0 | 0 |
| 2022 | 0 | 0 | 0 | 0 | 0 |
| 2023 | 0 | 0 | 0 | 0 | 0 |
| 2024 | 0 | 0 | 0 | 0 | 0 |
| 2025 | 0 | 0 | 0 | 0 | 0 |
| 2026 | 0 | 0 | 0 | 0 | 0 |
| 2027 | 605 | 269 | 202 | 470 | 1,546 |
| 2028 | 396 | 176 | 132 | 308 | 1,012 |
| 2029 | 418 | 186 | 139 | 325 | 1,067 |
| 2030 | 410 | 182 | 137 | 319 | 1,049 |
| 2031 | 382 | 170 | 127 | 297 | 975 |
| 2032 | 389 | 173 | 130 | 302 | 994 |
| 2033 | 410 | 182 | 137 | 319 | 1,049 |
| 2034 | 360 | 160 | 120 | 280 | 920 |
| 2035 | 403 | 179 | 134 | 314 | 1,030 |
| 2036 | 418 | 186 | 139 | 325 | 1,067 |
| 2037 | 418 | 186 | 139 | 325 | 1,067 |
| 2038 | 439 | 195 | 146 | 342 | 1,122 |
| 2039 | 418 | 186 | 139 | 325 | 1,067 |
| 2040 | 468 | 208 | 156 | 364 | 1,196 |
| Total | 5,933 | 2,637 | 1,978 | 4,614 | 15,162 |

Source: JICA (2020)

(2) Benefits from carbon sequestration by reforestation/ afforestation

The amount of carbon sequestration from the atmosphere by reforestation/ afforestation micro program was converted into the monetary values by using the market carbon price of US\$ 8.1/ t CO₂, which was used for reforestation/ afforestation project in the voluntary

carbon market in 2016⁷, to estimate the project benefits from carbon sequestration by reforestation/ afforestation. The calculation formula used for estimation is shown below.

$$\text{Benefits from Carbon sequestration} = \text{Estimated CO}_2 \text{ absorption from the atmosphere by reforestation/ afforestation} \times \text{USD } 8.1/\text{t CO}_2$$

As reforestation/ afforestation micro program of Activity 2.1.1 will be finished in 2027, it was assumed that the incremental project benefit of carbon sequestration would start in 2027 for conservative estimation. As a result, the total benefit from carbon sequestration during the project life span is estimated at US\$ 122,813.

Benefit from carbon sequestration by reforestation/ afforestation activities

3 Economic Cost

3.1 Project cost

As explained in Chapter 1 of this Annex, the SCF (Standard Conversion Factor) of 1.0 was used for estimation of the economic costs of the project components. Consequently, the total economic cost of the project was estimated at US\$ 15.4 million as shown below.

Table Economic Cost of the Project

(unit: US\$)

| | Cost Items (Output) | Financial Cost | SCF | Economic Cost |
|-------------|---------------------|----------------|-----|---------------|
| Component 1 | Activity 1.1.1 | 2,366,939 | 1.0 | 2,366,939 |
| | Activity 1.2.1 | 1,237,619 | 1.0 | 1,237,619 |
| | Activity 1.2.2 | 709,033 | 1.0 | 709,033 |
| Component 2 | Activity 2.1.1 | 6,885,182 | 1.0 | 6,885,182 |
| | Activity 2.2.1 | 229,829 | 1.0 | 229,829 |
| | Activity 2.3.1 | 1,331,517 | 1.0 | 1,331,517 |
| | Activity 2.4.1 | 24,773 | 1.0 | 24,773 |
| Component 3 | Activity 3.1.1 | 216,842 | 1.0 | 216,842 |
| | Activity 3.2.1 | 261,056 | 1.0 | 261,056 |
| | Activity 3.3.1 | 199,742 | 1.0 | 199,742 |

⁷ State of the Voluntary Carbon Markets 2017

| | Cost Items (Output) | Financial Cost | SCF | Economic Cost |
|--------------------|--|-------------------|-----|-------------------|
| Component 4 | Activity 3.4.1 | 342,972 | 1.0 | 342,972 |
| | Activity 4.1.1 | 28,350 | 1.0 | 28,350 |
| | Activity 4.1.2 | 267,778 | 1.0 | 267,778 |
| | Activity 4.2.1 | 140,404 | 1.0 | 140,404 |
| Project management | Preparatory works, planning, procurement, monitoring, and coordination | 912,811 | 1.0 | 912,811 |
| Contingency | 2.5% of total GCF cost | 243,322 | 1.0 | 243,322 |
| TOTAL | | 15,398,169 | | 15,398,169 |

Source: JICA (2020)

3.2 Operation and Maintenance Cost

Expenditures required for maintenance of the project effects at village and post-administrative levels were counted as operation and maintenance costs. Follow-up meetings, extension services and follow-up training, and regular meetings of the watershed management councils, which would be done on the initiative of MAF/DGFCIP, and Municipal Administrative Offices concerned, would be included. It was assumed that 1% of the Activities 1.1.1, 1.2.1, 1.2.2 and 2.1.1 would be allocated as annual O&M cost in the post-project period. The annual O&M cost in the post project period is estimated at USD 111,988/ year.

4. Cost-Benefit Analysis

4.1 Cash Flow Analysis

The cash flow of the economic cost and benefits during the project life span is presented in the table and figure shown below.

Cash Flow of Economic Costs and Benefits of the Project

| Year | Project Cost | | | O&M Cost | | Total Cost | Benefit | | | Total Benefit | Balance |
|------|---|-------------------|---------|---|-------------------|------------|-------------------|---------------------------------|--|---------------|------------|
| | Activities 1.1.1, 1.2.1 and 1.2.2 | Activity 2.1.1 | Others | Activities 1.1.1, 1.2.1 and 1.2.2 | Activity 2.1.1 | | Yield increase | Reduction of GHG emission | CO2 absorption by afforestation | | |
| 1 | 359,917 | 77,222 | 334,065 | | | 771,205 | 0 | 0 | 0 | 0 | -771,205 |
| 2 | 877,414 | 496,020 | 581,791 | | | 1,955,226 | 0 | 71,800 | 0 | 71,800 | -1,883,426 |

Cash Flow of Economic Costs and Benefits of the Project

Source: JICA (2020)

The composition of the present value of the benefits is shown in the figure below. The benefit from reduced CO₂ emissions and absorption of CO₂ from the atmosphere account for 40% of the total amount, while the rest, 60% of the total amount, derives from the benefit from increased maize production

Share of the Present Value of Benefit

Source: JICA (2020)

The economic rate of return (EIRR), cost-benefit ratio (B/C) and the net present values (NPV) were estimated by using the discount rate of 11.87% to validate the economic feasibility of the project. The results of the respective indicators are shown below.

Table Result of Economic Analysis each watershed

| Watershed | EIRR | B/C | NPV (US\$) |
|-----------|-------|------|------------|
| Overall | 18.7% | 1.41 | 4,673,127 |

Source: JICA (2020)

As the B/C is above 1.0, validity of the project to be implemented as public project is confirmed. The results also showed that the project economic viability turned positive from

the year 6 of the project, and the project was predicted to generate benefits throughout the lifetime period of the project.

4.2 Sensitivity Analysis

To evaluate the reliability and stability of the project effect from the economic viewpoint, a sensitive analysis was made with the following scenarios. Increase of work volume or project inputs and delay in the project activities due to unpredictable reasons are considered as the main factors affecting the project cost, while the price fall of carbon values and maize price in the markets is the major factor affecting the project benefit.

- Case 1: 10% increase of the project cost
- Case 2: 20% increase of the project cost
- Case 3: 10% reduction of the project benefit
- Case 4: 20% reduction of the project benefit
- Case 5: 10% increase of the project cost & 10% reduction of the project benefit
- Case 6: 10% increase of the project cost & 20% reduction of the project benefit
- Case 7: 20% increase of the project cost & 10% reduction of the project benefit
- Case 8: 20% increase of the project cost & 20% reduction of the project benefit

The calculation results of the sensitivity analysis are shown in the table below.

Result of Sensitivity Analysis of the Economic Analysis of the Project

| | EIRR | EIRR Difference from the Base Case | B/C | NPV (US\$) |
|---------------------------------|-------|---------------------------------------|------|---------------|
| Base Case | 18.7% | - | 1.41 | 4,673,127 |
| Case1: Cost +10% | 16.7% | - 2.0% | 1.28 | 3,531,623 |
| Case2: Cost +20% | 14.9% | - 3.8% | 1.17 | 2,390,118 |
| Case3: Benefit -10% | 16.5% | - 2.2% | 1.27 | 3,064,310 |
| Case4: Benefit -20% | 14.1% | - 4.6% | 1.13 | 1,455,493 |
| Case5: Cost +10% & Benefit -10% | 14.6% | - 4.1% | 1.15 | 1,922,805 |
| Case6: Cost +10% & Benefit -20% | 12.3% | - 6.4% | 1.03 | 313,988 |
| Case7: Cost +20% & Benefit -10% | 12.9% | - 5.8% | 1.06 | 781,301 |
| Case8: Cost +20% & Benefit -20% | 10.8% | - 7.9% | 0.94 | -827,517 |

Source: JICA (2020)

The sensitivity analysis indicates that the project may be still feasible even under the scenario of 10% reduction of project benefits plus 20% increase of project costs or 20% reduction of project benefits plus 10% increase of project costs.

5. Potential Impact on CO₂ Emissions from Deforestation

To assess the potential impact on CO₂ emissions from deforestation, the possible reduced CO₂ emissions from reduction of deforestation were estimated based on the same assumption used for the assessment of reduced CO₂ emissions from forest degradation. In the assessment, it was assumed that the deforestation rates in the respective watersheds would be constantly reduced by 20% per annum from one year after introduction of PLUP and cut to zero in the 6th year.

The changes in forest areas in the watersheds under the “with-project” and “without-project” conditions and the number of villages where the village-level NRM regulations is in place are shown in Table 1 and summarized below.

Estimated Changes in Forest Areas in the Watersheds

| Year | With-Project condition | Without-Project condition | Balance | No. of villages with NRM regulations |
|------|------------------------|---------------------------|-----------|--------------------------------------|
| 2021 | 111,442 ha | 111,442 ha | 0 ha | 13 |
| 2022 | 109,306 ha | 109,253 ha | 53 ha | 20 |
| 2023 | 107,382 ha | 107,135 ha | 247 ha | 21 |
| 2024 | 105,751 ha | 105,086 ha | 665 ha | 20 |
| 2025 | 104,483 ha | 103,103 ha | 1,380 ha | 0 |
| 2026 | 103,556 ha | 101,183 ha | 2,373 ha | 0 |
| 2027 | 102,904 ha | 99,323 ha | 3,581 ha | 0 |
| 2028 | 102,436 ha | 97,522 ha | 4,914 ha | 0 |
| 2029 | 102,059 ha | 95,777 ha | 6,282 ha | 0 |
| 2030 | 101,697 ha | 94,086 ha | 7,611 ha | 0 |
| 2031 | 101,347 ha | 92,448 ha | 8,899 ha | 0 |
| 2032 | 101,009 ha | 90,860 ha | 10,149 ha | 0 |
| 2033 | 100,683 ha | 89,321 ha | 11,362 ha | 0 |
| 2034 | 100,366 ha | 87,828 ha | 12,538 ha | 0 |
| 2035 | 100,060 ha | 86,379 ha | 13,681 ha | 0 |
| 2036 | 99,764 ha | 84,973 ha | 14,791 ha | 0 |
| 2037 | 99,478 ha | 83,609 ha | 15,869 ha | 0 |
| 2038 | 99,201 ha | 82,284 ha | 16,917 ha | 0 |
| 2039 | 98,933 ha | 80,998 ha | 17,935 ha | 0 |
| 2040 | 98,674 ha | 79,749 ha | 18,925 ha | 0 |

Source: JICA (2020)

As shown in Table 2, a total of 78,363 ha of existing forests, of which 16,242 ha are dense forest, are expected to be under the coverage of the village-level NRM regulations, which will be introduced and enhanced by Activities 1.1.1 and 1.2.1.

Tables 3 and 4 show the results of the calculation of reduced CO₂ emission from deforestation in the target watersheds in consideration of the discount factor of 20%. The results of the estimations indicate that around 993,000 tCO_{2eq} may be reduced by the project at the end of the project as shown below.

Reduced CO₂ Emissions from Deforestation

(Unit: ton CO_{2eq})

| Items | Laclo | Comoro | Tafara | Caraulun | Total |
|---|-----------|---------|-----------|-----------|-----------|
| Reduced CO ₂ Emissions from Deforestation after adjustment with DF (20%) in 2027 | 180,606 | 116,198 | 303,906 | 392,450 | 993,160 |
| Reduced CO ₂ Emission after adjustment with DF (20%) in 2040 | 1,107,442 | 490,088 | 1,639,118 | 1,984,912 | 5,221,560 |

Source: JICA (2020)

Furthermore, the estimated project cost (including co-finance) per tCO_{2eq} was US\$ 3.38/tCO_{2eq} for this project overall. Compared to the estimate that carbon prices are needed to be at least USD 40-80/tCO₂ by 2020 and USD50-100/tCO₂ by 2030 to reach the objectives of the Paris Agreement⁸, this proposed project can be said as a cost-effective way to reduce carbon emission. Since the project would further reduce the emission from deforestation as explained above, and moreover, increase CO₂ absorption by reforestation under CF, its cost effectiveness is expected to become higher. Hence, it also can be said to be very cost competitive within the forestry sector as well. Because many of the carbon pricing schemes for forests sets the price of US\$5 per tCO_{2eq} (Such as the Forest Carbon Partnership Facility

⁸ CPLC, Report of the High-Level Commission on Carbon Prices, May 29, 2017

and the GCF Result Based Payment pilot scheme). Given the fact that this project has not only mitigation but also adaptation effects, it can be said that this project is a cost-effective mitigation and adaptation project for climate change impacts.

6 Other Intangible Benefits/Impacts of the Project

In addition to the quantified benefits described above, the proposed project is expected to generate the following intangible benefits/ impacts, which could not be counted in the monetary value due to a lack of related data or difficulty in the conversion. Some of the major intangible benefits are highlighted below.

Table Summary of Intangible Benefits

| Expected Benefits | Project Component | Remarks |
|--|--|--|
| Protection of crops from damage caused by free grazing animals | Activities 1.1.1 and 1.2.1 | PLUP with participatory planning of the village regulations in Activity 1.1.1 and the follow-up meetings for capacity enhancement of local leaders in Activity 1.2.1 could reduce the number of cases of crop damage caused by animals, as those activities could regulate free animal grazing practices. |
| Stabilization of domestic water supply at village level | Activities 1.1.1 and 1.2.1 | Protection of forests, particularly dense forest, would contribute to the stabilization and improvement of water flow in the water sources used for drinking and domestic purposes. The experience of the JICA CBNRM Project indicates that the CBNRM approach would be effective in the restoration of dried sources. |
| Reduction of soil erosions | Activities 1.1.1, 1.2.1, and 2.1.1 | PLUP in Activity 1.1.1 would reduce the practice of shifting cultivation in the project villages, while hands-on training on climate resilient agriculture including techniques on sloping agricultural land techniques in Activity 2.1.1 could prevent the progress of soil erosion in the sloping farms in the villages. |
| Stabilization of peak flows and reduction of downstream flooding | Activities 1.1.1, 1.2.1, 1.2.2 and 2.3.1 | Sustainable forest protection and management including rehabilitation of degraded forests under Activities 1.1.1, 1.2.1, 1.2.2 and 2.3.1 at village and watershed levels would contribute to the stabilization of water flow of the mainstream in the target watersheds. |
| Reduction of domestic violence | Activities 1.1.1 and 1.2.1 | Likewise, PLUP with participatory planning of the village regulations in Activity 1.1.1 and the follow-up meetings for capacity enhancement of local leaders in Activity 1.2.1 could reduce the incidence of domestic violence as domestic violence issues would be monitored by local leaders. |
| Stabilization of food security | Activities 1.1.1, 1.2.1, and 2.1.1 | Hands-on training on climate change adaptation measures in Activity 2.1.1 would help local communities increase crop production or produce marketable products to either secure the means of livelihood or income generation. Sustainable natural resource management at village level through Activities 1.1.1 and 1.2.1 would enable local communities to have non-timber forest products which could be used for sale at markets or supplemental or emergency foods for household consumption. |
| Biodiversity conservation | Activities 1.1.1, 1.2.1, 1.2.2 and 2.3.1 | Protection of dense forests and improvement of degraded forests near dense forests would improve existing natural habitats of wild animals in the target watersheds. |
| Improvement of women's status in rural communities | Activities 1.1.1, 1.2.1, 1.2.2, 2.1.1, 2.2.1, 2.3.1, 2.4.1 and 3.2.1 | As proposed in the Gender Action Plan of the proposed project, the significant number of women would be involved in the project activities at village and government levels in a substantial way. Naturally, the project is expected to improve the status of women in local communities as well as the government institutions. |

Source: JICA (2020)

7 Financial Impacts on Household Economy

In order to assess the financial viability of the proposed project, financial impacts on household economy of local communities in the target villages are estimated assuming that local communities either adopt the climate resilient agriculture with sloping agricultural land techniques or establish a plantation to be used for a carbon offset project. To this end, the household budgets of the following two cases are estimated for assessment of the potential financial impacts of the project on household income.

Case 1: Households who replicate the climate resilient agriculture techniques in their own plot (0.5 ha)

Case 2: Households who establish a plantation for a carbon offset project in their own plot (0.5 ha)

Sales of surplus maize or saving of expenditures for buying maize are counted as cash earnings in Case 1, while the share of carbon credit sales is considered as the major source of income for Case 2. The tables below show the results of the estimation.

Household Budget Analysis of Case 1

| Items / Year | 2 nd year | 3 rd year on ward |
|---|--|--|
| 1. Gross income (Sales of Maize/ Saving of expenditures) per household *1 | | |
| 1) Incremental maize production | 300 kg (Laclo/Comoro) 350 kg (Tafara/ Caraulun) | 600 kg (Laclo/Comoro) 700 kg (Tafara/ Caraulun) |
| 2) Unit price of maize | US\$ 0.75/kg | US\$ 0.75/kg |
| 3) Sales of maize production | US\$ 225 (Laclo/Comoro) US\$ 263 (Tafara/ Caraulun) | US\$ 450 (Laclo/Comoro) US\$ 525 (Tafara/ Caraulun) |
| 2. Cost of Production | US\$ 0 | US\$ 0 |
| 3. Gross revenue per household | US\$ 225 (Laclo/Comoro) US\$ 263 (Tafara/ Caraulun) | US\$ 450 (Laclo/Comoro) US\$ 525 (Tafara/ Caraulun) |

Note *1 The same assumptions used for the calculation of benefits from increased maize production in Table 12-5 are used for estimation of household gross income.

Source: JICA (2020)

Household Budget Analysis of Case 2

| Items / Year | 1st year | 2 nd year | 3 rd year | 4 th year | 5 th ~10 th year |
|---|---------------------------|---------------------------|---------------------------|---------------------------|--|
| 1. Gross income (Share of sales of carbon credit trading) | | | | | |
| 1) Estimated CO ₂ absorption *1 | 4.2 tCO ₂ /HH | 2.75 tCO ₂ /HH | 2.90 tCO ₂ /HH | 2.85 tCO ₂ /HH | 2.65~2.90 tCO ₂ /HH |
| 2) Unit price of CO ₂ | US\$ 8.1/tCO ₂ | | | | |
| 3) Carbon sales | US\$ 34.0/HH | US\$ 22.3/HH | US\$ 23.5/HH | US\$ 23.0/HH | US\$ 21.5~23.5/HH |
| 2. Cost of maintenance | US\$ 0.0 | US\$ 0.0 | US\$ 0.0 | US\$ 0.0 | US\$ 0.0 |
| 3. Gross revenue | US\$ 34.0/HH | US\$ 22.3/HH | US\$ 23.5/HH | US\$ 23.0/HH | US\$ 21.5~23.5/HH |

Note: *1 Estimated by JICA based on the existing carbon offset project in Timor-Leste, "Halo Verde Timor Community Forest Carbon (2020)"

Source: JICA (2020)

The results of the assessments indicate that local communities in the target villages, particularly those who replicate the climate resilient agriculture techniques, would improve their household economy significantly. Households involved in a carbon offset project can also increase the gross revenue from carbon trading by expanding their plantations, though the estimated revenue of Case 2 is rather lower as compared to the ones of Case 1.
